

In dashboards like the one you're building, **percentages** (e.g., +4% from last week) typically show the **rate of change** or **growth** compared to a previous period. It tells users **how much the current value has increased or decreased** compared to a past reference point.

■ Meaning of the Percent Examples:

Let's say you have these numbers:

Metric	Current	Previous	Change
Male Youth	104	100	+4%
Female Youth	206	200	+3%
Married Youth	49	50	-2%
Unmarried Youth	105	100	+5%

These percentages are calculated as:

```
ini
CopyEdit
percent_change = ((current - previous) / previous) * 100
```

So:

- **Male Youth:** $((104 - 100) / 100) * 100 = +4\%$
- **Married Youth:** $((49 - 50) / 50) * 100 = -2\%$

💡 In Your App:

You could compare:

- This week vs last week
- This month vs last month
- Today vs yesterday

To make these percentages dynamic, you'd need to:

1. Fetch historical data (e.g., count from last week)
2. Compare with current count
3. Calculate the percentage difference
